

Best case per family: every defect is reachable by something, but the structural family alone leaves 8 of 12 out of reach

- best structural measure (reference-free)
- best similarity measure (needs a clean reference)

Bars are maxima, not averages: if the strongest measure in a family cannot see a defect, no measure in that family can. The similarity family reaches everything, but only where a clean reference exists -- which the benchmark has by construction and deployed code never does.
